A circuit breaker is a safety device used to protect a circuit from damage caused by an overload or a short circuit. When the breaker trips, the circuit will be disconnected from the source of electricity. The breaker is usually controlled by a switch or by a manually operated lever. The breaker may be protected by electronic trip units (ETUs) or by fuses. Electronic circuit breakers can be tripped by the breaker itself or by a remote signal. Electronic circuit breakers use the breaker's electronic trip function to sense the fault and activate the circuit breaker. Electromagnetic interference (EMI) has been used to reduce nuisance tripping on circuit breakers. Many circuit breakers for industrial applications, for example, have been equipped with an EMI filter to reduce the chance of nuisance tripping. One example of such a circuit breaker is disclosed in U.S. Pat. No. 6,823,503. A magnetic field is provided to conductively couple to ground. When the magnetic field is no longer coupled to ground, the electrical path is cut. The EMI filter is typically a hybrid filter in which a magnetic field is provided to extinguish the conductive path and a ground fault detector is connected to ground to direct the magnetic field to ground when ground fault occurs. When a supply is cut off, an open contact switch may not immediately trip the breaker. A breaker that is not tripped is typically referred to as a "non-tripped breaker". If the supply is not cut off, the breaker may not trip until the potential of the line side may become larger than the potential on the neutral side. Typically, the breaker will be tripped if the potential of the

line side exceeds the potential of the neutral f678ea9f9e
